## ABSTRACT

The purpose of this study was to determine whether it is both possible and cost-effective to revise middle-difficulty Graduate Record Examinations (GRE) discrete items in order to produce items of higher or lower difficulty. The basic procedure was to select items of a given difficulty and, by revising the distractors, make them easier or more difficult. It was found that it is significantly easier to increase the difficulty of middle-difficulty items than to reduce the difficulty of such items and that the difficulties of antonyms and analogies are much easier to manipulate than those of sentence completions. The evidence also suggests that producing harder analogies and antonyms by revising items in this manner would be a cost-effective procedure. Nine appendixes present definitions of GRE content categories, examples of revised items, statistical analysis results for revised items and the tests, pretest yields, and cost figures. Three tables illustrate the discussion. (SLD)

### **Abstract**

The purpose of this study was to determine whether it is both possible and cost-effective to revise middle-difficulty GRE discrete items in order to produce items of higher or lower difficulty. It was found that it is significantly easier to increase the difficulty of middle-difficulty items than to reduce the difficulty of such items, and that the difficulties of antonyms and analogies are much easier to manipulate than those of sentence completions. The evidence also suggests that producing harder analogies and antonyms by revising items in this manner would be a cost-effective procedure.

## Introduction

Over the past several years, assemblers of the verbal section of the GRE General Test have experienced increasing problems in meeting the current standard deviation of the delta specification, that is, meeting the statistical specification that calls for a relatively wide range of both hard and easy items in a verbal final form. These problems are the result of two somewhat related factors: a continuing inability to obtain, predictably and consistently, discrete items (analogies, antonyms, and sentence completions) that are very easy ( $\Delta$  6-8), and a similar, though even more serious, inability to obtain difficult discrete items ( $\Delta$  14-17).<sup>1</sup> In addition, the problems of assembly have been further complicated by losses of discrete items caused by the differential item functioning (DIF) statistic, a statistical screening for items that function differentially for subgroups of examinees; these losses, too, seem greatest at the extremes of the delta scale. The situation has, in fact, reached the point that assembly of the October 1989 final forms was delayed in order to wait for high delta items from the October 1988 pretests, because there was an insufficient pool of hard and easy items available for assembly. It is apparent that, even though modification of the standard deviation specification is under study and that statistical specifications based on item response theory (IRT) may relieve the problem to some degree in the future, the need to obtain items of a targeted difficulty, especially high delta items, is now critical and will remain so for the immediate future. The purpose of this study, therefore, is to address the continuing need for items with particular statistical characteristics (difficulty level) in the verbal measure. The study includes attempts at both raising and lowering difficulty levels of middle difficulty items (generating hard and easy items).

## Method

A large pool of middle-difficulty, pretested discrete items already exists and, under current pretesting conditions, can never be exhausted in assembling GRE final forms. This pool of items provided the material for the study. The basic procedure was to select items of difficulty  $\Delta$  9-10 and, by revising the distractors, make such items easier; similarly, items of difficulty  $\Delta$  12-13 were revised in an effort to make them more difficult. Items were selected as follows:

---

<sup>1</sup>Delta is an index of item difficulty based upon the percent of all candidates trying the item who answered it correctly. The principle advantage of delta over  $P_+$  (percent correct) lies in the fact that equal increments in delta, unlike  $P_+$ , may reasonably be assumed to represent equal increments in difficulty. This characteristic linearity of delta permits comparisons to be made between groups taking different test forms. A theoretical average delta for a 5-choice item is 12.0. (If 50% of the candidates know the answer and the other 50% answer by chance, 60% of the students will answer the item correctly. A  $P_+$  of .60 corresponds to a delta of 12.0) Deltas ordinarily range from 6.0 for very easy items (approximately 95% correct) to 13.0 for middle difficulty items (approximately 50% correct) to 20.0 for a very hard item (approximately 5% correct). The average range for the GRE verbal measure is 6.5 to 16.5, with a mean for the test of 12.0.

## General Content

<u>Type</u>	<u>Content Classification<sup>2</sup></u>	<u>Delta Range</u>	<u>Number of Items</u>	<u>Intended Outcome</u>
Sentence Completions	Art-Humanities	9-10	5	lower delta

	Art-Humanities	12-13	10	higher delta
	Human Rels	9-10	5	lower delta
	Human Rels	12-13	10	higher delta

## Item Characteristics

In the case of attempts to reduce the difficulty level of verbal discrettes, items were selected that had at least two strong distractors, that is, distractors that were attracting a significant number of test-takers. Distractors were weakened, in general, by relying on the judgments of experienced item writers to lower the vocabulary level and reduce the closeness of the distractor to the credited option. Specifically, for antonyms, words were chosen as distractors that were less semantically appropriate for either the stem or answer contexts; for sentence completion items, words were chosen as distractors that were less likely to appear in the contexts of the given sentences; and for analogy distractors, word pairs were chosen whose analogical relationships were less similar to those of the stem-answer pairs. (See Appendix B for examples of the revisions.)

For increasing the difficulty level of verbal discrettes, items were selected that had at least two weak distractors, that is, distractors that were attracting relatively few test takers. Strengthening a distractor, in general, consisted of relying on the judgment of experienced item writers to raise the vocabulary level and increase the closeness of the distractor to the credited option. For antonyms, words were chosen as distractors that were more semantically appropriate for either stem or answer contexts; for sentence completion items, words were chosen as

---

<sup>2</sup>These classifications have been selected as those that experience shows are least likely to yield high DIF values. See Appendix A for the definitions of the entire set of content categories for GRE verbal discrettes.

distractors that were more likely to appear in the contexts of the sentences; and for analogy distractors, pairs of words were chosen whose analogical relationships were more similar to those of the stem-answer pairs. (See Appendix C for examples of the revisions.)

The revised items were assembled into three experimental sections having the following characteristics:

- (1) Each section contained a long and short reading comprehension set typical of GRE verbal pretests and final forms; that is, each section maintained the appearance of a standard GRE pretest/final form.
- (2) Each section contained both easy and difficult discrete items, although not in the same proportions as in GRE verbal pretests and final forms.
- (3) Each section contained several science and practical affairs items in addition to the human relations and arts and humanities items being studied, again to preserve the appearance of the experimental sections as standard verbal pretests.

## Results

The complete quantitative results of this study can be found in Appendix D and Appendix E. Table 1 presents a summary of the most significant data, based on an analysis of those items (67 out of 72, or 93%) that had acceptable correlation coefficients ( $r_{bis} \geq .20$ ) after pretesting. All had acceptable  $r_{bis}$  before revision.

Our general finding is that manipulating the difficulty of a verbal discrete item in a desired direction by changing some of the distractors is possible. The ability to manipulate the difficulty, however, depends on a number of factors. First, as Table 1 shows, the average reductions in delta achieved during this study (-0.33) were smaller than the average increases in delta that were achieved (+0.78). Second, the difficulty levels of sentence completions (SNCP) proved significantly less manipulable than those of antonyms (ANT) or especially analogies (ANAL). Looking only at those items that were intended to be made harder, it can be seen in Table 1 that, whereas the difficulty levels of sentence completions were raised on average by only +0.28 delta points, the difficulty levels of antonyms and analogies together showed an average increase of +0.97 delta points. In addition, the standard deviations of the deltas of analogies and antonyms indicate that about 66% of all tries yielded increases of between 0 and 2 delta points.

We also compared the cost-effectiveness of the experimental method for producing difficult discretetes with the current method of pretesting. Two general methods of assessing the cost/benefits were used. First, we attempted to compare the dollar value (\$value) of the items produced by each method with the cost of production for each method. We assumed first that the experimental method would be used only on antonyms and analogies and only to increase deltas. We then used the frequency data given in Appendix F to determine what distribution of deltas, on average, could be expected from a set of 20 analogies and antonyms (one pretest's worth), revised from items with difficulties between  $\Delta 12$  and  $\Delta 13$  and having a mean delta of 12.6, and compared that to the standard yields of a normal pretest (the data from which the normal

**Table 1**  
**Statistical Results For Acceptable Items (N=67)**

Objective	Item Type	Avg Change in Delta	Range	StdDev
Make Easier	SNCP	-0.26	-1.4 to 1.5	0.92
	ANAL	-0.53	-2.1 to 1.1	1.00
	ANT	-0.25	-2.0 to 2.0	1.44
	ANAL+ANT	-0.38		
	AVG	-0.33		
Make Harder	SNCP	+0.28	-2.9 to 1.6	1.39

	ANT	+0.88	-1.0 to 3.1	0.99
	ANAL+ANT	+0.97		
	AVG	+0.78		
Control (N=26)		+0.12		

**Distribution of Items Whose Statistical Change Was in Intended Direction**

$\Delta$ Change	0.3-0.7	0.8-1.2	1.3-1.7	1.8-2.2	2.3-2.7	2.8-3.2	3.3-3.7	
# of items	8	15	9	5	0	3	1	= 41

and compared that to the standard yields of a normal pretest (the data from which the normal yields have been calculated are contained in Appendix G). Table 2 compares the two sets of yields.

As Table 2 demonstrates, the experimental method produces difficult items at significantly higher rates than those produced by standard pretesting. Using the calculation of the \$values of GRE items by delta range found in Appendix H, the \$values of the items produced by standard pretesting and by the experimental procedure can be compared (see Table 3). These values show that for one pretest's worth of analogies and antonyms (N=20), the experimental procedure produces items of 42% greater value than those produced by the standard pretesting procedure.

**Table 2**  
**Distribution of Deltas for 20 Hard Analogies and Antonyms:**  
**Standard versus Experimental**

Delta	Standard Frequency (Good $R_{\text{min}}$ )	Experimental Frequency (Good $R_{\text{min}}$ )
12	2.8	5.7
13	2.2	6.4
14	2.0	2.9
15	1.1	2.1
$\geq 16$	0.5	0.7

A comparison of the costs of production for each of these methods, however, yields unclear evidence about the cost-effectiveness of the experimental method. Because the experimental items can be produced more quickly than items produced through standard pretesting (1.2 hours/exp.item vs. 1.8 hours/std.item), test development costs for pretesting 20 analogies and antonyms are \$850 less for the experimental method than the costs of the standard method (\$7,660 exp. cost vs. \$8,550 std. cost). However, before a cost/benefits ratio can be calculated, the value of the pretested items used must be factored into the costs. For standard pretesting, this value is \$0 (because there are no pretested items), yielding a cost/benefits ratio of \$8,550:\$13,457 or \$1:\$1.57. (See Table 3.)

For the experimental items, initial value can be calculated in a number of ways. Given the large GRE pool of  $\Delta 12$  analogies and antonyms and the fact that in a standard year of 20 pretests and 4 final forms 100% more  $\Delta 12$ s and 24% more  $\Delta 13$ s will be produced than will be needed, one reasonable assessment of the initial value of the discretes used in the experimental method is also \$0. This results in a cost/benefits ratio of \$7,660:\$19,173 or \$1:\$2.50. Using the determination of values of GRE discretes of various deltas listed in Appendix H, however, results in an initial value for the items used in the experimental method of \$10,985 (14  $\Delta 12$ s, and 6  $\Delta 13$ s), and a cost/benefits ratio of \$18,645:\$19,173 or \$1:\$1.03. Thus, using the first estimation of initial value, the experimental method produces approximately one-half times more benefit per dollar spent than does the standard method. By the second estimation of initial value, however, the experimental method produces only about the same benefit per dollar spent as does the standard method. We believe that estimating the initial value of the revised items at \$0 is the more reasonable way to proceed, because large portions of the GRE pool of middle-difficulty items will, in all probability, never be used.

A second way to calculate the cost/benefits of the experimental method is to determine how many fewer pretests could be run if a mixture of standard method pretests and experimental method pretests were used. Using the data found in Appendix I, it was determined that a mixture of 14 standard pretests and 3 experimental pretests would best yield the requisite number of items

**Table 3**

\*See Appendix H.

\*\*See Appendix G.

\*\*\*See Appendix F.

at the various deltas where they are needed.<sup>3</sup> If the value of the pretested items used in the experimental pretests is set at \$0, the savings per year would be \$62,550 ( $\$20,000$  [T.D. costs/pretest]  $\times 3$  [pretests saved/yr] +  $\$850$  [T.D. savings/exp.pretest]  $\times 3$  [exp. pretests/yr]). If the values listed in Appendix H are used, the savings per year would be \$29,596 ( $\$62,550 - \$10,985$  [value of items/exp. pretest]  $\times 3$  [exp. pretests/yr]).

The preceding shows that a consistent estimate of the savings that could be achieved by including the experimental method in GRE pretesting is difficult to come by, mainly because there is no one obvious way to determine the value of the already pretested items reused in the experimental pretests. Our best guess, using the figures for pretest savings, is that a mixture of standard and experimental pretests could save the GRE programs between \$30,000 and \$60,000 per year if we can extrapolate from the data on which our study is based, and if we can safely cut

<sup>3</sup>Because the experimental items were written in content categories chosen to minimize DIF, it is possible that the yields listed in Appendix I for the experimental pretests might in practice be lower. However, because the pool of pretested items from which the experimental items were picked was deliberately restricted to older items for which no DIF data were available, it is likely that these experimental items show more DIF than would occur if revision was made of items for which DIF information was already known.

back to 17 pretests per year.

### Conclusions

The results of our research indicate that the experimental procedure can be used to enrich the GRE discrete pool, but only with the following provisos: (1) The method should be used only to produce higher delta items; and (2) the method should not be applied to sentence completion items. We believe that this method is likely to be a cost-effective way to produce more difficult analogy and antonym discretely, and that it can be effectively introduced by dedicating three pretests worth of analogies and antonyms per year to items revised in the ways suggested in this study.

We also believe that further research is in order before the benefits of this method are certain. We recommend (1) trying a more extensive study using all four content categories and focusing specifically on increasing the difficulty of antonyms and analogies; (2) studying the ability to increase the difficulty of discretely that are not middle range in difficulty (i.e., is it possible by using the same techniques to raise  $\Delta 14$  and  $\Delta 15$  items to  $\Delta 15$ ,  $\Delta 16$ , and  $\Delta 17$  items?); (3) doing a more extensive investigation of the possibility of making  $\Delta 10$  and  $\Delta 11$  analogies easier using this method; and (4) using this method of research to determine, for each item type, the degree to which distractors affect item performance (i.e., it seems from data on SNCP items that performance on those items is not much affected by the distractors).

**APPENDIX A: DEFINITIONS OF GRE CONTENT CATEGORIES****Art-Humanities**

This category includes words (or, in the case of sentence completions, issues and ideas) that are most likely to be used or discussed in the discourse of, or discourse about, the fine and applied arts (painting and architecture, for example), literature, philosophy, religion, and other such fields.

**Social Studies and Practical or Everyday Life**

This category includes words (or, in the cases of sentence completions, issues and ideas) that are most likely to be used or discussed in the discourse of, or discourse about, such fields as communications, business, politics and government, economics, and transportation.

**Science and Nature**

This category includes words (or, in the case of sentence completions, issues and ideas) that are most likely to be used or discussed in the discourse of, or discourse about, such fields as biology, chemistry, physics, geology, and the theoretical and applied sciences, such as mathematics and medicine.

**Human Relationships and Feelings**

This category includes words (or, in the case of sentence completions, issues and ideas) that concern emotions, interpersonal relationships, or analyses of character.

ITEM: V-099427

Original Item

In the midst of so many evasive comments, this forthright statement, whatever its intrinsic merit, plainly stands out as -----.

- (A) an anomaly
- (B) an inaccuracy
- (C) an inference
- (D) a misnomer
- (E) a pattern

BASE N	OMIT	A *	B	C	D	E	M-TOT	SCALE	$\Delta E$	CRIT

EXPERIMENTAL ANALOGIES AND ANTONYMS WITH ACCEPTABLE RBIS**

<b>Delta Range</b>	<b># Produced in Exp.Pretsts</b>	<b>Freq/ Pretst*</b>	<b># Produced with Good DIF</b>	<b>Freq/ Pretst*</b>
<11.0	0	0.0	0	0.0
11.0 - 11.9	1	0.7	0	0.0
12.0 - 12.9	8	5.7	6	4.3
13.0 - 13.9	9	6.4	7	5.0
14.0 - 14.9	4	2.9	4	2.9
15.0 - 15.9	3	2.1	3	2.1
≥16.0	1	0.7	1	0.7
<b>Unacceptable Rbis</b>	2	1.4	2	1.4
<b>TOTAL</b>	28		23	

\*Frequency/pretest calculated by dividing the number of items produced in each delta range by 28/20 ([total # hard ANALS & ANTS in exp. pretests]/[# ANALS & ANTS per 1 pretest]). This gives the frequency to be expected were an entire pretest's worth of analogies and antonyms revised to be made harder according to the experimental procedure.
